on b

lining the first trench with dielectric material;

substantially filling the first trench with conductive material to form a gate electrode of the field effect transistor:

forming a body region having a second conductivity type in the substrate; forming a source region having the first conductivity type inside the body region and adjacent to the first trench;

forming a second trench adjacent to said source region, the second trench defined by sidewalls extending into the body region and a bottom, which terminates below the source region and in contact with the body region; and

filling the second trench with high conductivity material for making contact to the body region.

Please cancel claims 4, 5 and 9-11.

Please amend claim 13 as follows:

D

13. (Once Amended) A process for manufacturing a trench field effect transistor comprising the steps of:

etching a first trench in a substrate having a first conductivity type;

lining the first trench with a layer of dielectric material;

substantially filling the trench with polysilicon;

implanting impurities of a second conductivity type into the substrate to form a body region having the second conductivity type over the substrate;

implanting impurities of the first conductivity type inside the body region to form a source region adjacent to the first trench;

etching a second trench through the source region and into the body region, the second trench defined by sidewalls and a bottom, which terminates in contact with the body region; and

filling the second trench with metal making contact with both the source region and the body region.
